# For the non-recursive version:

```

```

# Time Complexity:  $O(n)$  since we need to iterate from 2 to n to calculate the
Fibonacci number at position n.
# Space Complexity:  $O(n)$  since we are storing all the Fibonacci numbers up to the
nth position in the list.

# For the recursive version:

# Time Complexity:  $O(2^n)$  since at each level of the recursion tree, the number
of function calls doubles.
# Space Complexity:  $O(n)$  considering the space taken up by the function call
stack.

# In terms of efficiency, the non-recursive version is much more efficient than
the recursive one for large values of n. This is because the recursive version
recalculates the same values multiple times, leading to exponential time
complexity.

# Function to solve the fractional knapsack problem

    return randomized_quicksort(left) + middle + randomized_quicksort(right)

# Analysis
def analyze_sorting_algorithm(sort_function, array):
    start_time = time.time()
    sorted_array = sort_function(array)
    end_time = time.time()
    return sorted_array, end_time - start_time

# Test the algorithms

```

```

test_array = [3, 2, 1, 5, 4, 8, 7, 6]
sorted_array_det, time_taken_det =
analyze_sorting_algorithm(deterministic_quicksort, test_array)
sorted_array_rand, time_taken_rand =
analyze_sorting_algorithm(randomized_quicksort, test_array)

# Print results
print("Deterministic Quicksort:")
print("Sorted Array:", sorted_array_det)
print(f"Time taken: {time_taken_det:.6f} seconds")
print("\nRandomized Quicksort:")
print("Sorted Array:", sorted_array_rand)
print(f"Time taken: {time_taken_rand:.6f} seconds")

def generate_random_array(start, end, size):
    array = []
    for i in range(size):
        array.append(random.randint(start, end))
    return array

# In the analyze_sorting_algorithm function, the sorting function is passed as an
argument. This function can be any sorting algorithm, including the
deterministic_quicksort function. When you call sort_function(array), it is
replaced by the actual sorting function you pass to it. Therefore, if you pass
deterministic_quicksort as the sort_function argument, it will be executed during
the sort_function(array) call.

# Here's how the execution flows:

# start_time = time.time() captures the current time before the sorting operation
begins.

# sorted_array = sort_function(array) calls the sorting function that was passed
as an argument. If deterministic_quicksort was passed as sort_function, it will
execute the code inside the deterministic_quicksort function, which sorts the
array using the deterministic Quicksort algorithm.

# end_time = time.time() records the time after the sorting is completed.

# end_time - start_time calculates the time taken for the sorting process.

# Finally, the function returns both the sorted array and the time taken for the
sorting operation as a tuple.

```

So, the deterministic_quicksort function gets executed inside the analyze_sorting_algorithm function when you pass it as an argument to sort_function. The timing is done around the execution of the sorting function to measure the time taken by that specific sorting algorithm.

Deterministic (Classic) Quick Sort:

```
# def partition(arr, low, high):
#     pivot = arr[low]
#     left = low + 1
#     right = high
#     done = False

#     while not done:
#         while left <= right and arr[left] <= pivot:
#             left = left + 1
#         while arr[right] >= pivot and right >= left:
#             right = right - 1
#         if right < left:
#             done = True
#         else:
#             arr[left], arr[right] = arr[right], arr[left]

#     arr[low], arr[right] = arr[right], arr[low]
#     return right
```

```
# def deterministic_quick_sort(arr, low, high):
#     if low < high:
#         pivot_index = partition(arr, low, high)
#         deterministic_quick_sort(arr, low, pivot_index - 1)
#         deterministic_quick_sort(arr, pivot_index + 1, high)
```

Example usage:

```
# arr = [3, 6, 8, 10, 1, 2, 1]
# deterministic_quick_sort(arr, 0, len(arr) - 1)
# print("Deterministic Sorted array:", arr)
```

Randomized Quick Sort:

```
# import random
```

```
# def randomized_partition(arr, low, high):
#     random_index = random.randint(low, high)
#     arr[random_index], arr[low] = arr[low], arr[random_index]
#     return partition(arr, low, high)
```

```

# def randomized_quick_sort(arr, low, high):
#     if low < high:
#         pivot_index = randomized_partition(arr, low, high)
#         randomized_quick_sort(arr, low, pivot_index - 1)
#         randomized_quick_sort(arr, pivot_index + 1, high)

# # Example usage:
# arr = [3, 6, 8, 10, 1, 2, 1]
# randomized_quick_sort(arr, 0, len(arr) - 1)
# print("Randomized Sorted array:", arr)

```

Given a bank customer, build a neural network-based classifier that can determine whether they will leave or not in the next 6 months.

Dataset Description: The case study is from an open-source dataset from Kaggle. The dataset contains 10,000 sample points with 14 distinct features such as CustomerId, CreditScore, Geography, Gender, Age, Tenure, Balance, etc. Link to the Kaggle project: <https://www.kaggle.com/basilevdedicated/bank-customer-churn-modeling> Perform following steps:

1. Read the dataset.
2. Distinguish the feature and target set and divide the data set into training and test sets.
3. Normalize the train and test data.
4. Initialize and build the model. Identify the points of improvement and implement the same.
5. Print the accuracy score and confusion matrix.

```
In [46]: import pandas as pd
import numpy as np
import seaborn as sns
import matplotlib.pyplot as plt #Importing the libraries
```

```
In [47]: df = pd.read_csv("Churn_Modelling.csv")

TITLE: Implement Gradient Descent Algorithm to find the local minima of a function. For example, find the local minima of the function $y=(x+3)^2$ starting from the point $x=2$.

AIM: The aim of this practical is to illustrate the implementation of the Gradient Descent algorithm for locating local minima of a given function. This involves understanding the gradient descent method, performing iterations to converge towards a local minimum, and evaluating the effectiveness of the algorithm in the context of the function $y = (x + 3)^2$ starting from the initial point ($x = 2$).

OBJECTIVES: Based on above main aim following are the objectives

1. **Understanding Optimization Techniques:** Develop a solid understanding of optimization methods, with a focus on the Gradient Descent algorithm. Grasp the concept of finding local minima in mathematical functions through iterative updates.
2. **Algorithm Implementation:** Implement the Gradient Descent algorithm practically. Apply it to the function $y = (x + 3)^2$, beginning with an initial value of ($x = 2$), and observe how the algorithm converges towards a local minimum.
3. **Analyzing Convergence:** Examine the iterative behavior of the Gradient Descent algorithm. Gain insights into how the algorithm iteratively refines the value of (x) by utilizing the gradient of the function.
4. **Algorithm Evaluation:** Evaluate the effectiveness of the Gradient Descent algorithm in successfully identifying the local minimum of the given function. Compare the obtained result with the anticipated theoretical solution.

Prerequisite:

Basic of Python, Concept of Gradient Descent Algorithm

Software Requirements:

Anaconda with Python 3.7

Hardware Requirement:

PIV, 2GB RAM, 500 GB HDD

Theory Concepts:

What is gradient descent ?

It is an optimization algorithm to find the minimum of a function. We start with a random point on the function and move in the **negative direction** of the **gradient of the function** to reach the **local/global minima**.

Example:

Question : Find the local minima of the function $y=(x+5)^2$ starting from the point $x=3$

Solution : We know the answer just by looking at the graph. $y = (x+5)^2$ reaches its minimum value when $x = -5$ (i.e when $x=-5$, $y=0$). Hence $x=-5$ is the local and global minima of the function.

Now, let's see how to obtain the same numerically using gradient descent.

Step 1 : Initialize $x = 3$. Then, find the gradient of the function, $dy/dx = 2*(x+5)$.

Step 2 : Move in the direction of the negative of the gradient ([Why?](#)). But wait, how much to move?

For that, we require a learning rate. Let us assume the **learning rate** $\rightarrow 0.01$

Step 3 : Let's perform 2 iterations of gradient descent

Initialize Parameters :

$$X_0 = 3$$

$$\text{Learning rate} = 0.01$$

$$\frac{dy}{dx} = \frac{d}{dx} (x + 5)^2 = 2 * (x + 5)$$

Iteration 1 :

$$X_1 = X_0 - (\text{learning rate}) * \left(\frac{dy}{dx}\right)$$

$$X_1 = 3 - (0.01) * (2 * (3 + 5)) = 2.84$$

Iteration 2 :

$$X_2 = X_1 - (\text{learning rate}) * \left(\frac{dy}{dx}\right)$$

$$X_2 = 2.84 - (0.01) * (2 * (2.84 + 5)) = 2.6832$$

Step 4 : We can observe that the X value is slowly decreasing and should converge to -5 (the local minima).

Implementing Gradient Descent in Python

Importing libraries

```
import numpy as np
import matplotlib.pyplot as plt
```

We then define the function f(x) and its derivative f'(x) –

```
def f(x):
    return (x+3)**2

def df(x):
    return 2*x + 6
```

$F(x)$ is the function that has to be decreased, and df is its derivative (x). The gradient descent approach makes use of the derivative to guide itself toward the minimum by revealing the function's slope along the way.

The gradient descent function is then defined.

```
def gradient_descent(initial_x, learning_rate, num_iterations):
    x = initial_x
    x_history = [x]

    for i in range(num_iterations):
        gradient = df(x)
        x = x - learning_rate * gradient
        x_history.append(x)

    return x, x_history
```

The starting value of x , the learning rate, and the desired number of iterations are sent to the gradient descent function. In order to save the values of x after each iteration, it initializes x to its original value and generates an empty list. The method then executes the gradient descent for the provided number of iterations, changing x every iteration in accordance with the equation $x = x - \text{learning_rate} * \text{gradient}$. The function produces a list of every iteration's x values together with the final value of x .

The gradient descent function may now be used to locate the local minimum of $f(x)$ –

```
initial_x = 2
learning_rate = 0.1
num_iterations = 50

x, x_history = gradient_descent(initial_x, learning_rate, num_iterations)

print("Local minimum: {:.2f}".format(x))
```

Output

Local minimum: -3.00

In this illustration, x is set to 2 at the beginning, with a learning rate of 0.1, and 50 iterations are run. Finally, we publish the value of x , which ought to be close to the local minimum at $x=-3$.

Plotting the function $f(x)$ and the values of x for each iteration allows us to see the gradient descent process in action –

```
#Create a range of x values to plot
x_vals = np.linspace(-1, 5, 100)

#Plot the function f(x)
plt.plot(x_vals, f(x_vals))

# Plot the values of x at each iteration
plt.plot(x_history, f(np.array(x_history)), 'rx')

#Label the axes and add a title
plt.xlabel('x')
plt.ylabel('f(x)')
plt.title('Gradient Descent')

#Show the plot
plt.show()
```

Conclusion: Thus we have implemented Gradient Descent Algorithm to find the local minima of a function $y=(x+3)^2$ starting from the point $x=2$ that is -3 .

Implement K-Means clustering/ hierarchical clustering on sales_data_sample.csv dataset. Determine the number of clusters using the elbow method.

```
In [198]: import pandas as pd
import numpy as np
import seaborn as sns
import matplotlib.pyplot as plt
#Importing the required libraries.
```

```
In [199]: from sklearn.cluster import KMeans, k_means #For clustering
from sklearn.decomposition import PCA #Linear Dimensionality reduction.
```

```
In [200]: df = pd.read_csv("sales_data_sample.csv") #Loading the dataset.
```

Preprocessing

```
In [201]: df.head()
```

```

Plotting the Elbow Plot to determine the number of clusters.

```
In [219]: distortions = [] # Within Cluster Sum of Squares from the centroid
K = range(1,10)
for k in K:
    kmeanModel = KMeans(n_clusters=k)
    kmeanModel.fit(df)
    distortions.append(kmeanModel.inertia_) #Appeding the inertia to the Distortions
```

```
In [220]: plt.figure(figsize=(16,8))
plt.plot(K, distortions, 'bx-')
plt.xlabel('k')
plt.ylabel('Distortion')
plt.title('The Elbow Method showing the optimal k')
plt.show()
```

As the number of k increases Inertia decreases.

Observations: A Elbow can be observed at 3 and after that the curve decreases gradually.
